eGFR_{Cys}, estimated glomerular filtration rate based on cystatin C

Bold font for hazard ratio (95% confidence interval) indicates statistical significance.

^a Adjusted for age, sex, race, body mass index, systolic blood pressure, anti-hypertensive medication use, diabetes status, total cholesterol, high-density lipoprotein cholesterol, current cigarette smoking status, first measurement of the respective filtration marker. eGFR was included in the model as linear spline terms with two knots at 60 and 90 mL/min/1.73 m². For the three marker average, all three filtration markers (eGFR-creatinine, eGFR-cystatin C, 1/β₂-microglobulin) were included in the model. All covariates were assessed at ARIC study visit 2 (1990-1992).

^b Analyses exclude prevalent cases of the respective outcome.

^c Three Marker Average: mean of percent change in estimated glomerular filtration rate-creatinine, estimated glomerular filtration rate-cystatin C, and 1/β₂-microglobulin
