 eJournal club provides a timely and interactive electronic journal club experience by offering a forum in which CJASN readers have the opportunity to converse with the featured study authors. Visit ejc.cjasn.org to learn more.

On the Cover

What's the diagnosis? A 36-year-old patient on chronic hemodialysis noted right elbow pain associated with numbness and hypoesthesia of the right forearm and hand. The patient underwent conventional X-ray of the right elbow, which demonstrated large soft-tissue calcifications (cover image). Prior to returning to dialysis, the patient previously had a functioning kidney transplant for 10 years. While on hemodialysis, the patient maintained a calcium-phosphate product of 80-90 mg²/dL² despite maximal dosage of non-calcium-based phosphate binders and a hemodialysis bath calcium concentration reduced to 1 mmol/L for each session (3×4h per week). Review of total-body X-rays detected additional soft-tissue calcifications in both hips and hands. Extravascular calcification in patients maintained on chronic hemodialysis is considered to be a major cardiovascular risk factor. Such calcium deposits within tissues are thought to result from a complex imbalance between calcification inducers and inhibitors. Notably, calcification is more likely to occur in the presence of higher circulating levels of phosphate, calcium, fibroblast growth factor 23 (FGF23) and osteocalcin, and lower levels of matrix-Gla protein, fetuin-A and osteoprotegerin. Very often, soft-tissue calcifications reflect severe bone disorders, including low bone turnover with increased serum calcium and phosphate levels. In the present case, soft-tissue calcifications of the right elbow were surgically removed because of the associated pain, inflammation and nerve compression. The patient rapidly recovered mobility of his hand and the pain progressively resolved. Additional efforts were undertaken to improve the patient's adherence to low phosphate diet, which slightly improved the calcium-phosphate product to 70 mg²/dL². However, no significant impact on the soft-tissue calcifications in the hips and hands was noted. Daily sessions of home hemodialysis were initiated to further increase phosphorus removal.
